The Expert Committee noted that concomitant chemotherapy and radiotherapy using cisplatin or carboplatin is the standard of care for treating early-stage head and neck cancers and that both agents are effective radiosensitizers. The evidence presented in the application evaluated overall survival and found only a limited overall survival benefit associated with the addition of cisplatin or carboplatin to radiotherapy compared with radiotherapy alone, with no significant difference between the two agents. However, the Committee noted that the most relevant outcome measure for chemoradiation is local control of the disease, for which both cisplatin and carboplatin are associated with benefit, particularly in early-stage disease. More evidence is available for cisplatin, and it is already included on the EML for head and neck cancer as a radiosensitizer. However, cisplatin is associated with relevant acute and late toxicities and cannot be used in the considerable proportion of patients who are unfit for this chemotherapy. The Committee considered that carboplatin can be an alternative option as a radiosensitizer for patients in whom cisplatin is contraindicated or not tolerated, due to its different and better tolerated toxicity profile. The Expert Committee also acknowledged that the Cancer Working Group supported the inclusion of carboplatin on the EML as an alternative option to cisplatin for this indication. The Expert Committee therefore recommended the inclusion of carboplatin as a radiosensitizer for head and neck cancers in patients unable to tolerate cisplatin.

As part of the comprehensive review of cancer medicines undertaken by the Expert Committee in 2015, cisplatin was added to the complementary list of the EML for use as a radiosensitizer in treatment protocols for head and neck cancer. Compared with postoperative radiotherapy alone, the Committee considered that the benefits associated with the addition of cisplatin, in terms of local and regional control rates, disease-free survival and progression-free survival, were of clinical relevance. The Committee also
considered that the use of primary combined chemotherapy with cisplatin and radiation was associated with a clinical benefit, compared with radiation alone, in patients who have unresectable tumours (1).

Head and neck cancers include many site-specific tumours, including oral cavity and oropharyngeal cancers. However, about 90% of all head and neck cancers are squamous cell carcinomas (2). This group of cancers accounts for 89 000 new cases and 450 000 deaths annually and is the sixth most common cancer worldwide (3). Although the incidence for nasopharyngeal cancers has decreased over the past 20 years, the incidence of oropharyngeal and hypopharyngeal cancers, and lip and oral cavity cancers has increased (4). The incidence of head and neck cancer varies markedly by geographical location; it is noticeably more frequent in South Asia and less frequent in western sub-Saharan Africa and Andean Latin America (4,5). The prognosis of head and neck cancers depends largely on the location of the tumour and its stage. Overall, the 5-year survival is 66.9%. However, localized stages have a 5-year survival ranging from 62% to 96% depending of the anatomic site, while metastatic disease has a 5-year survival in the range of 20–40% (6).

The applicants conducted a literature search for randomized controlled trials and systematic reviews of platinum-based chemotherapy for head and neck cancer, and conducted a meta-analysis of the results. Risk of bias was assessed using the Cochrane Collaboration Risk of Bias Tool, and judgements about precision, consistency, directness and likelihood of publication bias were made following the GRADE approach. Seventeen systematic reviews (used to identify relevant studies) were identified (7–23). No new trial evidence was found since the 2015 application. Eight trials, in seven publications, provided data to estimate the effect of cisplatin or carboplatin on overall survival. Six trials assessed the effect of cisplatin (24–28), while two evaluated carboplatin (29,30). In almost all of the trials, platinum chemotherapy was used as a single chemotherapy agent; in one trial, it was used in combination with 5-fluorouracil (30). Participants in most of the trials had locally advanced disease. The meta-analysis showed that the addition of cisplatin or carboplatin to radiotherapy may increase overall survival by 2 months (hazard ratio (HR) 0.95, 95% confidence interval (CI) 0.80 to 1.12; low-certainty evidence).

Twenty-six trials reporting data on adverse events were identified from the systematic reviews and included in the meta-analysis. The addition cisplatin or carboplatin to radiotherapy may increase the risk of adverse events (risk ratio (RR) 1.16, 95% CI 1.01 to 1.16; low-certainty evidence). In absolute terms, 52 more patients per 1000 experience adverse events. The most common adverse events were mucositis, skin toxicity, dysphagia and stomatitis.

A meta-analysis of 93 randomized trials (17 346 participants) provides a comprehensive evaluation of the effect of chemotherapies in locally advanced head and neck cancer (31). The meta-analysis showed that chemotherapy, when compared with radiotherapy alone, was associated with a relevant benefit in overall survival, with about 4.5% more patients being alive at 5 years (absolute improvement). This benefit was larger for concomitant chemotherapy, whereas the observed benefit for induction and adjuvant chemotherapies was uncertain. Among chemotherapies, concurrent high-dose cisplatin (100 mg/m² on days 1, 22 and 43 during radiotherapy) was the most effective regimen compared with 5-fluorouracil and carboplatin. Based on these results, concurrent chemoradiotherapy with cisplatin became the preferred choice for the treatment of patients with locoregionally advanced squamous cell carcinoma of the head and neck in the clinical practice guidelines of the European Head and Neck Society, the European Society of Medical Oncology and European Society for Radiotherapy and Oncology, and the National Comprehensive Cancer Network (32,33). However, platinum-based concomitant chemoradiotherapy has acute and late toxic effects. Adding cisplatin to radiotherapy is associated with increased gastrointestinal, haematological, neurological and renal adverse effects. This toxicity adds to the toxicity caused by radiotherapy. In randomized controlled trials, the addition of high-dose cisplatin doubled the number of cases of severe acute mucositis (34). More than one third of patients developed severe acute dysphagia (35). Severe adverse effects are also associated with decreased compliance, with a relevant proportion of patients (up to a third) unable to receive all planned cycles of chemotherapy (34,36). Late toxicity is also extremely problematic when cisplatin-based induction chemotherapy is followed by cisplatin-based concomitant chemoradiotherapy, as it decreases the quality of life of patients for the
rest of their lives. For these reasons carboplatin is frequently used in routine clinical practice when cisplatin is not tolerated or contraindicated. Based on the above-mentioned meta-analysis, carboplatin and 5-fluorouracil are considered acceptable alternatives as they are associated with gains in survival (31). Carboplatin has a similar mode of action to cisplatin, but it is associated with less acute and late toxicities (e.g. ototoxicity, nephrotoxicity, neurotoxicity and emesis) (37,38). Carboplatin can be used in patients with impaired kidney function and can be easily dosed based on glomerular filtration rate (39).

### Cost / cost effectiveness

No economic evaluation studies were identified.

### WHO guidelines

WHO guidelines for the treatment of head and neck cancers are not available.

### Availability

Carboplatin has marketing approval from many national regulatory agencies, including the Australian Therapeutic Goods Administration, the European Medicines Agency, Health Canada, the Japanese Pharmaceuticals and Medical Devices Agency and the United States Food and Drug Administration. It is currently included on the Model List for other indications and is available in branded and generic forms.

### Other considerations

The EML Cancer Medicines Working Group noted that concomitant chemotherapy and radiotherapy using cisplatin or carboplatin is the standard of care for the treatment of head and neck cancers. Both agents are effective radiosensitizers, cisplatin is more active, but also more toxic than carboplatin. The available evidence suggests that there are no significant differences between agents in terms of survival. The Working Group therefore advised that it supported the inclusion of carboplatin on the Model List as an alternative treatment option to cisplatin for concomitant chemoradiation therapy of head and neck cancers in patients unable to tolerate cisplatin. Comments were received from the WHO Department of Noncommunicable Diseases. The technical department concurred with the conclusion that carboplatin provides similar clinical benefit to cisplatin, with a different safety profile and less toxicity. The technical department agreed that the addition of carboplatin to the EML for use in the treatment of head and neck cancer as a radiosensitizer primarily relates to patients unable to tolerate cisplatin.
