Valproic acid (sodium valproate)

**Expert Committee recommendation**

The Expert Committee recognized the serious risks associated with the use of valproic acid in pregnant women and in females of child-bearing potential. While most of the evidence and regulatory measures described in the application are from Europe, the risks with valproate when prescribed to women and girls of child-bearing potential are equally relevant globally. Sodium valproate is currently listed as an essential medicine for use in the treatment of epilepsy and bipolar disorder, indications for which it has regulatory approval. Furthermore, valproic acid is recommended for the management of epilepsy and bipolar disorder in the WHO mhGAP intervention guide. These guidelines also include a strong recommendation to avoid the use of valproic acid in women of child-bearing age. The Committee considered that inclusion of a cautionary note with the listings of valproic acid to indicate that use should be avoided in pregnant women and females of child-bearing potential was appropriate, although it is aware the EML does not replace prescribing information issued by national medicine regulatory authorities. The Committee did not recommend transferring the listing of valproic acid from the core to the complementary list. The Committee considered doing so may have negative implications for access to valproic acid and undermine its important role in the management of epilepsy and bipolar disorder, particularly in resource-constrained settings, where access to valproate and alternative treatments is limited. The Committee supported the need for patient and prescriber education on the risks and appropriate use of valproic acid, including its use for off-label indications, but considered this to be a responsibility of the relevant national decision-makers. The Committee recommended the following note be included with the listings for valproic acid on the EML and EMLc: “Avoid use in pregnancy and in women and girls of child-bearing potential unless alternative treatments are ineffective or not tolerated, because of the high risk of
Valproic acid has been included on the EML as a medicine for epilepsy since 1979. It was included on the first EMLc for this indication in 2007. Since 1997, valproic acid has also been included on the EML for the treatment of bipolar disorder in adults.

Valproic acid is used in the treatment of labelled indications of epilepsy and bipolar disorder, as well as off-label indications such as migraine prophylaxis, neuropathic pain and behavioural disturbances in dementia. Valproic acid is a known human teratogen, and its use during pregnancy is associated with an increased risk of birth defects and neurodevelopmental disorders in children exposed to the drug in utero (1–7). To address these risks, regulatory agencies in many parts of the world, including Europe, the United Kingdom and the USA have issued guidance and/or restrictions on the use of valproic acid in pregnancy and in women and girls of child-bearing potential (8–11).

The application reproduced the warnings, precautions and contraindications for the use of valproic acid in female children, adolescents and women of child-bearing potential and in pregnancy from past and current summaries of product characteristics. The application also briefly described two studies that evaluated the effects of antiepileptic medicines, including valproic acid, on cognitive and neurodevelopmental outcomes in children exposed to the drugs in utero. The NEAD study was a prospective, observational multicentre study conducted in the United Kingdom and USA that evaluated the effects of commonly prescribed antiepileptic medicines (carbamazepine, lamotrigine, phenytoin or valproic acid) on cognitive outcomes in children up to 6 years of age born to mothers receiving these medicines during pregnancy (12). The primary outcome of the study was intelligence quotient (IQ) of children at age 6. A total of 244 children were included in the age 6 analysis. The study found that the age 6 IQ was lower in children exposed to valproic acid compared with children exposed to other antiepileptic drugs. Children exposed to valproate also did poorly on measures of verbal and memory abilities compared with children exposed to other antiepileptic drugs. These effects of valproic acid were dose-dependent. Another prospective, observational study of children born to women with epilepsy compared with a control group of children born to women without epilepsy was conducted in the United Kingdom (1). This study reported an increased risk of neurodevelopmental disorders in children exposed to valproic acid as monotherapy (adjusted odds ratio (aOR) 6.05, 95% CI 1.65 to 24.53) and as polytherapy (aOR 9.97, 95% CI 1.82 to 49.40) compared with controls. Autistic spectrum disorder was the most frequent diagnosis. No significant increase in neurodevelopmental disorders was found among children exposed to carbamazepine or lamotrigine as monotherapy.

The WHO mhGAP intervention guide, version 2.0 for mental, neurological and substance use disorders in non-specialized health settings (13) includes recommendations for the use of valproic acid in the treatment of epilepsy and manic episodes in bipolar disorder. The guide also includes warnings to avoid the use of valproic acid in women of child-bearing age and during pregnancy and breastfeeding due to the known risks to the child. The WHO Pharmaceuticals Newsletter (14) states the following in relation to the use of valproic acid in pregnancy or in females of child-bearing potential. “Medicines containing valproate (e.g. sodium valproate, valproic acid, divalproex) should be avoided in pregnant women or in females of child-bearing potential, unless alternative treatments are ineffective or not tolerated, because of the high risk of birth defects (such as spina bifida, facial, skull, limb and heart malformations) and developmental disorders in infants who are exposed to valproate in the womb. When alternative treatments are not available or appropriate, female patients prescribed valproate medicines should be made aware of the risk and use effective contraception methods.”
