An application from the WHO Global TB Programme requested the removal from the EML and EMLc of capreomycin and kanamycin for use in treatment regimens for multidrug-resistant tuberculosis (MDR-TB). The proposed deletions were in alignment with recommendations in the 2019 update of the WHO consolidated guidelines on drug-resistant tuberculosis treatment (1). One of the key outcomes of the revision was a re-classification of medicines recommended for inclusion in regimens for MDR-TB/RR-TB. Capreomycin and kanamycin had previously been recommended as Group B, second-line injectable agents along with amikacin and streptomycin (2). The 2019 guidelines no longer recommend the use of capreomycin and kanamycin as treatment options. Use of capreomycin and kanamycin was associated with poorer outcomes when compared with regimens not containing these medicines in the latest data analysis. The Expert Committee recommended the deletion of capreomycin and kanamycin from the complementary list of the EML and EMLc, noting the advice of the WHO Global TB Programme that their use is no longer recommended in WHO guidelines due to evidence that regimens involving these agents were associated with worse outcomes compared with regimens that did not include them, and that fully oral regimens should be preferred for most patients.
